Using ANOVA in R

ANOVA in R.

Log into sage.moravian.edu and open a new R Notebook.

Before we get started, we should load tidyverse as usual. You will want to load this every time you start working in R.

library(tidyverse)

```
-- Attaching core tidyverse packages ----- tidyverse 2.0.0 --
          1.1.1
                                2.1.4
v dplyr
                   v readr
v forcats
           1.0.0
                    v stringr
                                1.5.0
v ggplot2 3.4.1
                   v tibble
                                3.2.1
v lubridate 1.9.2
                    v tidyr
                                1.3.0
          1.0.1
v purrr
-- Conflicts ----- tidyverse_conflicts() --
x dplyr::filter() masks stats::filter()
x dplyr::lag()
                masks stats::lag()
i Use the conflicted package (<a href="http://conflicted.r-lib.org/">http://conflicted.r-lib.org/</a>) to force all conflicts to become errors
```

The setup

Recall the scenario from the previous screencast about ANOVA. You have stores in three locations and want to see how their customer satisfaction compares. You randomly survey customers from each store. Is there a difference in customer satisfaction between the stores?

To answer this we'll explore the data a little, then use the ANOVA procedure to see if we have strong evidence.

First load the data. You can find a link to the data on Canvas. First, right click the link to copy the url, then use the read_csv command to load the data from the URL. Let's put it in a data frame named SurveyData

SurveyData <- read_csv("https://raw.githubusercontent.com/moravian-mspa/MGMT555/master/m3_ANOVA_in_R/Su

```
Rows: 58 Columns: 3
-- Column specification ------

Delimiter: ","

chr (1): Location

dbl (2): Person, Rating

i Use `spec()` to retrieve the full column specification for this data.

i Specify the column types or set `show_col_types = FALSE` to quiet this message.
```

Understand the data

What does the data look like? To get a quick idea we can use the head command and R will print the first 10 lines of the data.

```
head(SurveyData)
```

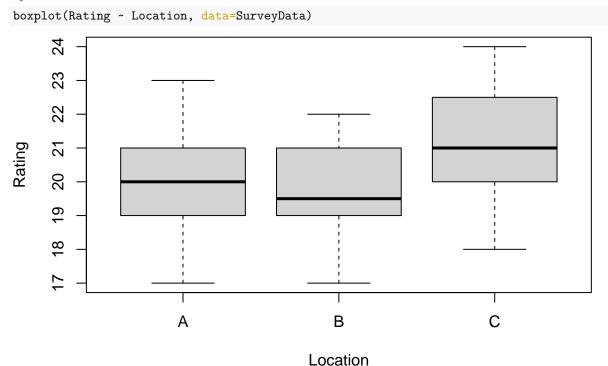

```
# A tibble: 6 x 3
```

	Person	Location	Rating
	<dbl></dbl>	<chr></chr>	<dbl></dbl>
1	1	A	23
2	2	A	21
3	3	A	21
4	4	C	21
5	5	C	21
6	6	A	17

So we have a column labeled "Person" with a number, a "Location" column with three choices, and a "Rating" column with the satisfaction rating from a customer at that Location.

Next a boxplot can be helpful to get a sense of the data. Note the command below uses numbers from the Rating column, but groups the data by Location.

Can you see where I told the function where to find the data? Can you see where I told it to group the data by Location?

The centers for each region seem different, but are they really? All the boxplots do overlap to some extent.

Running an ANOVA test

Let's use an ANOVA test to decide if we have evidence that there is a difference in the means. Before we run the test we should be sure all the necessary conditions are met.

Requirements:

- 1. **Independent samples**: Since these are different stores where customers were sampled randomly we are ok here.
- 2. **Normality**: the sample sizes are pretty large, but we can still think about normality. Based on the boxplots, there is not a significant skew, so we are safe here.
- 3. Standard deviations: remember, the largest should be less than twice the smallest. Let's check that. The tapply command applies a command to data in a table column, grouping by another column. So with the one command below we compute the standard deviation for each region.

```
tapply(SurveyData$Rating, SurveyData$Location, sd)
```

```
A B C
1.596126 1.274434 1.627613
```

So the largest standard deviation is store C at 1.63 and the smallest is store B at 1.27. The ratio between these is less than 2 so this requirement is met.

Running the test

The assumptions of ANOVA are met, so let's actually run the test. In the first line we run the test with the aov command and store the results with the name analysis. The next line asks for a summary of the analysis. R stores a lot more information about the test, but this is all we really need.

```
analysis <- aov(Rating ~ Location, data=SurveyData)
summary(analysis)</pre>
```

```
Df Sum Sq Mean Sq F value Pr(>F)
Location 2 24.86 12.428 5.414 0.00714 **
Residuals 55 126.25 2.295
---
Signif. codes: 0 '***' 0.001 '**' 0.05 '.' 0.1 ' ' 1
```

Recall ANOVA uses the F distribution, but most important for us is the p-value. We find a p-value of 0.00714 which is quite small. So we reject the null hypothesis.

In other words, there is a less than 1% chance that we would see these differences just because of random chance alone. It looks like something significant is going on here.

In other words, we have strong evidence that at least two of the stores have different means. That's all an ANOVA can tell us. But which ones are different?

We'll use the code below to generate a confidence interval for the mean of each store. Remember the tapply command from above? The t.test command is a convenient way to generate a confidence interval.

```
tapply(SurveyData$Rating, SurveyData$Location, t.test)
```

\$A

```
One Sample t-test

data: X[[i]]
t = 57.558, df = 20, p-value < 2.2e-16
alternative hypothesis: true mean is not equal to 0
95 percent confidence interval:
    19.32107 20.77417
sample estimates:
mean of x
    20.04762

$B

One Sample t-test

data: X[[i]]
t = 65.656, df = 17, p-value < 2.2e-16
alternative hypothesis: true mean is not equal to 0</pre>
```

```
95 percent confidence interval:
19.08846 20.35598
sample estimates:
mean of x
19.72222

$C

One Sample t-test

data: X[[i]]
t = 56.945, df = 18, p-value < 2.2e-16
alternative hypothesis: true mean is not equal to 0
95 percent confidence interval:
20.47867 22.04764
sample estimates:
mean of x
21.26316
```

We see Stores A and B have significant overlap in their confidence intervals, so I'm not convinced their means are different. The only stores whose intervals do not overlap are B and C. Since our ANOVA told us at least two means must be different, we can say we have strong evidence that the mean for Store B is less than the mean for Store C.
